

EXECPLAN — Business Model Report

Version: 1.0 · **Date:** June 2026 · **Stage:** Working MVP complete (backend, web, mobile)

1. The problem

Organizations that run operational plans — emergencies, guard rotations, maintenance windows, inspection campaigns, transport operations — still activate them with phone trees, WhatsApp groups, and paper checklists. The failure modes are predictable and expensive: nobody knows in real time who has actually mobilized, tasks silently stall because the assignee never saw them, substitutes are called too late or not at all, and after the event there is no defensible record of who responded, when, and what got done. In safety-critical contexts such as municipal storm response or facility emergencies, the gap between “the plan was activated” and “the right people are working the right tasks” is measured in minutes that matter.

Generic project-management tools do not solve this. They assume desk workers planning weeks of work, not shift workers who must confirm readiness in seconds from a phone. Mass-notification platforms solve the alerting half but stop at “message delivered” — they do not generate tasks, track execution, rank teams, or escalate to substitutes. EXECPLAN’s thesis is that the activation cycle is a product of its own.

2. The product and its value proposition

EXECPLAN converts an operational plan into executable tasks, assigns them to teams resolved from a live shift roster, activates the plan in one tap, and tracks execution on a live dashboard. Its differentiating mechanics are the readiness button — a single «أنا جاهز» tap is the one and only definition of “responded” — and disciplined escalation: a non-responder who ignores five call attempts is automatically replaced by his pre-designated substitute, who receives his own task list instantly. The dashboard answers the three questions an operations chief actually asks: who has mobilized, which teams are ahead or behind, and what is overdue.

The value proposition differs by buyer. For the operations director it is situational awareness and a faster, auditable mobilization. For the compliance and audit function it is a timestamped record of every notification, call attempt, response, escalation, and task completion. For team leaders and members it is clarity — one screen, one button, one

checklist, in Arabic, designed for non-technical users. For the IT department it is a system that runs on a single modest server with no exotic infrastructure.

A genuine and defensible differentiator is that the product is Arabic-first by construction — right-to-left throughout, Arabic labels written for field staff rather than translated, Kuwait timezone and shift conventions native — while carrying a complete English locale for mixed workforces. International incident-management platforms treat Arabic as an afterthought; for GCC government buyers this is frequently a tender requirement, not a preference.

3. Target market and segments

The beachhead market is Kuwait, expanding across the GCC. The primary segments, in order of fit, are: municipal and government operations (storm and flood response, public-works mobilization, event security plans); facilities and property management groups running guard, maintenance, and inspection rotations across sites; utilities and oil-and-gas contractors with shift-based field crews and strict emergency-response obligations; and hospitals and large campuses with code-activation procedures. Each of these already owns written plans and shift rosters — EXECPLAN digitizes assets they have, rather than asking them to invent new process.

The buying pattern in this region favors direct, relationship-driven sales into government and large enterprises, often through local system-integrator partners, with tenders that reward Arabic-language capability, local hosting or on-premises deployment, and demonstrable working software. The completed MVP — installable on a customer’s own VPS in an afternoon — is itself a sales asset in this environment.

Market-size figures for this niche are not reliably published, so honest sizing is bottom-up and assumption-driven: Kuwait alone has six governorates’ municipal operations, dozens of large facilities-management firms, the major oil-sector contractors, and public hospitals — plausibly 150–300 organizations matching the ideal customer profile, before counting the wider GCC, where the comparable population is several times larger. These are planning assumptions to be validated in pilot conversations, not market research claims.

4. Revenue model and pricing architecture

The natural model is B2B SaaS subscription with an on-premises licensing variant for government buyers who cannot use shared cloud. A three-part pricing architecture fits how value scales:

Tier	Intended buyer	Composition (indicative)

Team	Single department or site	Flat monthly fee covering up to ~50 users, cloud-hosted, in-app notifications only
Operations	Multi-team organizations	Per-active-user monthly pricing, SMS/voice/WhatsApp channels (usage passed through with margin), priority support
Government / Enterprise	Ministries, municipalities, oil sector	Annual on-premises license plus maintenance (typically 18–22% of license per year), deployment and training services, SLA

Two structural points matter more than specific price levels, which should be set against pilot feedback. First, notification channels (voice calls, SMS, WhatsApp) carry per-message telecom costs; pricing them as metered usage with a margin, on top of the platform fee, aligns revenue with the customer's most valuable moments — activations — and the MVP's provider-interface architecture was built precisely to meter this. Second, the on-premises tier converts the region's data-sovereignty requirement from an obstacle into a premium product: license-plus-maintenance deals are larger, stickier, and standard practice for government software here. Professional services — plan digitization, roster onboarding, drills and training — form a third revenue line that also drives activation of the subscription itself.

5. Go-to-market

Phase one is two to three paid pilots in Kuwait — ideally one municipal operations unit and one facilities or contracting firm — priced low but never free, scoped to one real plan each (a storm-response plan is the ideal first case given seasonal urgency), with success defined as a live activation drill where response rate and time-to-mobilization are measured before and after. The drill itself is the demo: a room watching the dashboard fill with green as field staff tap the readiness button is the most persuasive sales artifact this product can produce.

Phase two converts pilots into references and pursues government tenders through local SI partners, who handle hosting, support, and relationships in exchange for a reseller margin. Phase three expands to Saudi Arabia and the UAE, where the same Arabic-first positioning applies at a much larger scale, likely requiring local hosting partnerships to satisfy each country's data regulations.

6. Competitive landscape

Competition arrives from three directions. Mass-notification and critical-event platforms

(Everbridge, AlertMedia and similar) are strong at alerting, weak at task execution, priced for Western enterprises, and not Arabic-first. Generic work-management tools (Asana, Monday, Trello and the like) can be bent toward checklists but have no concept of shift rosters, activation snapshots, readiness acknowledgment, or substitute escalation, and overwhelm non-technical field staff. The third and most serious competitor is the status quo — WhatsApp groups and phone calls — which is free and familiar; the counter is the audit trail, the escalation automation, and the dashboard, none of which WhatsApp can fake. EXECPLAN's defensible position is the intersection: activation-cycle mechanics that the notification platforms lack, operational simplicity that the PM tools lack, and Arabic-first regional fit that both lack.

7. Cost structure and unit economics

The cost base is favorable. The product runs on a single VPS per tenant (or a shared cluster for cloud tiers), so infrastructure cost per customer is tens of dollars monthly against subscriptions priced in the hundreds or thousands. Notification telecom costs are passed through with margin by design. The dominant costs are people: founding engineering to complete the roadmap (real notification channels, scheduled escalation, push notifications), and one bilingual sales-and-success role early, since government sales cycles in the region run six to eighteen months and pilots need hand-holding. Gross margins should behave like standard B2B SaaS (high seventies to eighties percent) once telecom pass-through is netted out; the real economic risk is sales-cycle length, not unit economics.

8. Key metrics

The metrics that prove the model, in order: pilot-to-paid conversion rate; time-to-mobilization improvement measured in drills (the product's headline ROI number); activations per customer per month (engagement, and the driver of metered channel revenue); net revenue retention as customers add departments and plans; and for the public-sector line, tender win rate with reference customers attached.

9. Risks and mitigations

The principal risks are commercial rather than technical. Long government procurement cycles are mitigated by leading with smaller private facilities-management deals for cash flow while tenders mature. Dependence on a readiness behavior change among field staff is mitigated by the deliberate one-button design and by selling drills as part of onboarding. Telecom integration costs and regulations (especially for voice calls in Kuwait) require a licensed local gateway partner — a known, solvable dependency the provider-interface architecture isolates. Competitive response from global platforms adding Arabic is a real

medium-term threat; the moat is regional depth (shift conventions, on-prem government deployments, local support) rather than the language toggle alone. Finally, single-market concentration in Kuwait argues for opening one second GCC market within the first eighteen months.

10. Roadmap to revenue

With the MVP complete, the sequence is: deploy a demo tenant on a public server and digitize two showcase plans (weeks, not months); sign two to three paid pilots ahead of the next storm season; integrate one real notification channel (WhatsApp Business or a local SMS gateway) since pilots will demand it immediately; convert pilots to annual contracts and capture the drill metrics as case studies; then pursue the first government tender with an SI partner carrying the on-premises offering. The technical roadmap items — scheduled escalation, push notifications, the FinalReport module — map one-to-one onto what paying customers will ask for first, which is exactly where an MVP should leave a business standing.
